[Title of the Utility Model]      Resin Molded Type Luminescent Body

[Summary]

[Purpose]      To prevent the axial intensity from being lowered when making the lens diameter smaller to realize narrow directivity and high axial intensity.

[Structure]      A light emitting semiconductor element 2 is mounted in a recessed portion 1a which is sealed with a resin 5 of which the refractive coefficient is smaller than that of the molding resin 4. The interface between the molding resin 4 and the resin 5 forms a concave surface. Light emitted at the light emitting semiconductor 2 is condensed through the interface between the molding resin 4 and the resin 5 to be led to a lens of the molding resin 4.

## DETAILED DESCRIPTION

---

[Detailed explanation of a design]

[0001]

[Industrial Application]

This design is related with the plastic-molded-type emitter which closed the luminescence semiconductor device by the translucency resin.

[0002]

[Description of the Prior Art]

The typical plastic-molded-type emitter used for the emitted type display of light etc. is shown in drawing 5. This plastic-molded-type emitter has two leadframes 1 and 1. Crevice 1a is prepared in the point of one leadframe 1, and wirebonding of the luminescence semiconductor device 2 mounted here is carried out to it to the leadframe 1 of another side. And the point of leadframes 1 and 1 is embedded in the resin 4 for closure focusing on the luminescence semiconductor device 2 in crevice 1a. An apical surface is formed in the shape of a semi-sphere, and the resin 4 for closure constitutes the convex lens for condensing.

[0003]

It is condensed with the lens constituted with the resin 4 for closure, and the light emitted from crevice 1a of the luminescence semiconductor device 2 or the element mounting section shows desired directivity and transverse-plane intensity. Condensing with this lens is governed by L value (distance from a luminescence side to a lens center), and the diameter of a lens. Directivity and transverse-plane intensity are mostly determined by these two factors, generally, when all light enters in a lens, the diameter of a lens takes for becoming small, directivity becomes narrow gradually, and transverse-plane intensity goes up them. These directional characteristics are shown in drawing 6. Using the relation between the diameter of a lens, and directivity, as shown in drawing 7, the plastic-molded-type emitter of narrow directivity and high transverse-plane intensity which set only the center section of the transverse plane of the resin 4 for closure to lens 4a is also developed.

[0004]

[Problem(s) to be Solved by the Device]

However, in the conventional plastic-molded-type emitter, if it becomes small exceeding a value with the diameter of a lens, a part of light emitted from the crevice of a luminescence semiconductor device or the element mounting section will not carry out incidence to a lens (refer to drawing 7). Consequently, the fall of transverse-plane intensity is caused. Moreover, if the diameter of a lens is made small and directivity is narrowed since the electrode section of an element does not emit light when an electrode uses the luminescence semiconductor device located at the center, the directivity will serve as 2 mountain type as shown in drawing 8. Therefore, transverse-plane intensity falls also in this case.

[0005]

This design is originated in view of this situation, and it aims at offering the plastic-molded-type emitter which can prevent the fall of the transverse-plane intensity at the time of making the diameter of a lens small.

[0006]

[Means for Solving the Problem]

In the plastic-molded-type emitter with which the luminescence semiconductor device was mounted in the crevice, the plastic-molded-type emitter concerning this design closes the inside of the aforementioned crevice with the resin of a low refractive index rather than the resin for closure, and is characterized by considering as the concave surface which hollowed the interface of the resin and the aforementioned resin for closure in the luminescence semiconductor device side.

[0007]

[Example]

Hereafter, the example of this design is explained with reference to a drawing. Drawing of longitudinal section of the plastic-molded-type emitter which drawing 1 shows one example of this design, and drawing 2 are graphs which show the directional characteristics of the plastic-molded-type emitter of drawing 1.

[0008]

A plastic-molded-type emitter has two leadframes 1 and 1. Crevice 1a is prepared in the point of one leadframe 1, and wirebonding of the luminescence semiconductor device 2 mounted here is carried out to it by the gold stick 3 to the leadframe 1 of another side. The point of leadframes 1 and 1 is embedded in the resin 4 for closure except for the inside of crevice 1a. The apical surface center section located in the transverse plane of crevice 1a is projected in the shape of a semi-sphere, and the resin 4 for closure constitutes minor diameter convex lens 4a for condensing. The refractive index of the resin 4 for closure is 1.5.

[0009]

In crevice 1a of a leadframe 1, it fills up with the resin 5 of a low refractive index rather than the resin 4 for closure. When the refractive index of the resin 4 for closure is 1.5, as a resin 5, the precoat resin for stress relaxation (refractive index 1.4) can be used. The resin 5 closes the luminescence semiconductor device 2 in crevice 1a, and has stuck it to the resin 4 for closure. The interface of the resin 4 for closure and a resin 5 is the concave surface which became depressed in the

luminescence semiconductor device 2 side.

This concave surface can be formed using the surface tension of a resin 5.

[0010]

In this plastic-molded-type emitter, it reflects by the inside of crevice 1a, and the light emitted from the luminescence semiconductor device 2 passes the resin 5 in crevice 1a, and it carries out incidence to the resin 4 for closure. The light which the interface of the resin 4 for closure and a resin 5 is a concave surface, and carries out incidence to the resin 4 for closure from a resin 5 since the refractive index of a resin 5 is smaller than the refractive index of the resin 4 for closure is condensed by the interface. That is, a resin 5 functions as a false lens for condensing.

Therefore, in the conventional plastic-molded-type emitter, the light protruded from lens 4a of the resin 4 for closure can also be drawn in lens 4a. Therefore, the fall of the transverse-plane intensity at the time of making the diameter of a lens small is prevented, and narrow directivity and high transverse-plane intensity are realized.

Moreover, even when an electrode is located at the center of the luminescence semiconductor device 2, directive 2 mountain inclination (refer to drawing 8) is eased by the condensing function of the interface of the resin 4 for closure, and a resin 5, and the increase in transverse-plane intensity is achieved by it.

[0011]

Drawing 3 is drawing of longitudinal section of the plastic-molded-type emitter in which other examples of this design are shown. This plastic-molded-type emitter is an SMD (Surface Mount Device) type, and has the insulating substrate 7 in which the pattern 6 by plating was formed. Crevice 7a for mounting the luminescence semiconductor device 2 is prepared in the front face of an insulating substrate 7. Wirebonding of the luminescence semiconductor device 2 in crevice 7a is carried out by the gold streak 3 to the pattern 6. Into crevice 7a, it fills up with the resin 5 with a refractive index smaller than the resin 4 for closure, and let the interface with the resin 4 for closure be a concave surface. In addition, the laminating of the resin 4 for closure is carried out to the front face of an insulating substrate 7, and the core is set to convex lens 4a. Also in this plastic-molded-type emitter, narrow directivity and high transverse-plane intensity are realized by the condensing function of the interface of the resin 4 for closure, and a resin 5.

[0012]

Drawing 4 is drawing of longitudinal section showing still more nearly another example of this design. This example is using the whole transverse plane of the resin 4 for closure as the lens to the above-mentioned example using a part of transverse plane of the resin 4 for closure as a lens.

[0013]

[Effect of the Device]

As mentioned above, when based on the plastic-molded-type emitter concerning this design. By having closed the inside of the crevice where the luminescence semiconductor device was mounted with the resin of a low refractive index rather than the resin for closure, and having made the interface of the resin and the aforementioned resin for closure into the concave surface. Since a false concave lens is formed in the incidence side of the lens by the resin for closure and a condensing function is added, even if the diameter of a lens is small, incidence of the whole quantity of the luminescence quantity of light can be carried out to a lens, and transverse-plane intensity can be raised further. Moreover, even when an electrode is located at the center of a luminescence semiconductor device, directive 2 mountain inclination is eased by the condensing function of a false lens, and the increase in transverse-plane intensity is achieved by it. Therefore, narrow directivity and high transverse-plane intensity are realized.

DESCRIPTION OF DRAWINGS

---

[Brief Description of the Drawings]

[Drawing 1] It is drawing of longitudinal section of the plastic-molded-type emitter in which one example of this design is shown.

[Drawing 2] It is the graph which shows the directional characteristics of the plastic-molded-type emitter of drawing 1.

[Drawing 3] It is drawing of longitudinal section of the plastic-molded-type emitter in which other examples of this design are shown.

[Drawing 4] It is drawing of longitudinal section showing still more nearly another example of this design.

[Drawing 5] It is drawing of longitudinal section of the conventional plastic-molded-type emitter.

[Drawing 6] It is the graph which shows the directional characteristics of the conventional plastic-molded-type emitter.

[Drawing 7] It is drawing of longitudinal section of the plastic-molded-type emitter which aimed at conventional narrow directivity and high transverse-plane intensity.

[Drawing 8] It is the graph which shows directivity in case an electrode is located at the center of a luminescence semiconductor device.

(54)【考案の名称】 樹脂封止型発光体

(57)【要約】

【目的】 レンズ径を小さくしたときの正面強度の低下をなくし、狭指向性および高正面強度を実現する。

【構成】 発光半導体素子2がマウントされる凹部1a内を、封止用樹脂4よりも屈折率が小さい樹脂5で封止する。封止用樹脂4と樹脂5との界面を凹面とする。発光半導体素子2で発せられた光を、封止用樹脂4と樹脂5との界面で集光して、封止用樹脂4のレンズに導く。
